

I have reviewed the meta-analysis data in the spreadsheet. A lot of work you and Dr. Imhoff did!! The results are very robust and strong! The very high negative predictive value which is universally observed in any subgroup analyses is so impressive. This is the highest accuracy result I've ever seen achieved with the non-invasive testing in female population.

Observed specificity and negative predictive value in women <65 is excellent despite of relatively high CAD prevalence in this meta-analysis. Some of 12 "false-positive" cases in this population may have true ischemia due to microcirculation disturbance which conventional coronary angiography cannot detect.

This meta-analysis strengthens the evidence of clinical accuracy of 3DMP technology and will raise the awareness and recognition of this valuable device in the field.
